

# Searching (Binary Search)

T#11

# Binary Search

- Input:
  - A sorted array  $A[ ]$  of size  $n$
  - A value  $b$  to be searched for in  $A[ ]$
- Output:
  - If  $b$  is found, the index  $k$  where  $A[k]=b$
  - If  $b$  is not found, return  $-1$
- Definition: An  $A[ ]$  is said to be *sorted* if:  
$$A[0] \leq A[1] \leq A[2] \leq \dots \leq A[n-1]$$

# Binary Search

Example: sorted array of integer keys. Key=7.

[ 0 ]	[ 1 ]	[ 2 ]	[ 3 ]	[ 4 ]	[ 5 ]	[ 6 ]
3	6	7	11	32	33	53

# Binary Search

Example: sorted array of integer keys. Target=7.

[ 0 ]	[ 1 ]	[ 2 ]	[ 3 ]	[ 4 ]	[ 5 ]	[ 6 ]
3	6	7	11	32	33	53

Find approximate midpoint

# Binary Search

Example: sorted array of integer keys. Target=7.

[ 0 ]	[ 1 ]	[ 2 ]	[ 3 ]	[ 4 ]	[ 5 ]	[ 6 ]
3	6	7	11	32	33	53

Is 7 = midpoint key? NO.

# Binary Search

Example: sorted array of integer keys. Target=7.

[ 0 ]	[ 1 ]	[ 2 ]	[ 3 ]	[ 4 ]	[ 5 ]	[ 6 ]
3	6	7	11	32	33	53

Is  $7 < \text{midpoint key}$ ? YES.

# Binary Search

Example: sorted array of integer keys. Target=7.

[ 0 ]	[ 1 ]	[ 2 ]	[ 3 ]	[ 4 ]	[ 5 ]	[ 6 ]
3	6	7	11	32	33	53

Search for the target in the area before midpoint.

# Binary Search

Example: sorted array of integer keys. Target=7.

[ 0 ]	[ 1 ]	[ 2 ]	[ 3 ]	[ 4 ]	[ 5 ]	[ 6 ]
3	6	7	11	32	33	53

Find approximate midpoint

# Binary Search

Example: sorted array of integer keys. Target=7.

[ 0 ]	[ 1 ]	[ 2 ]	[ 3 ]	[ 4 ]	[ 5 ]	[ 6 ]
3	6	7	11	32	33	53

Target = key of midpoint? NO.

# Binary Search

Example: sorted array of integer keys. Target=7.

[ 0 ]	[ 1 ]	[ 2 ]	[ 3 ]	[ 4 ]	[ 5 ]	[ 6 ]
3	6	7	11	32	33	53

Target < key of midpoint? NO.

# Binary Search

Example: sorted array of integer keys. Target=7.

[ 0 ]	[ 1 ]	[ 2 ]	[ 3 ]	[ 4 ]	[ 5 ]	[ 6 ]
3	6	7	11	32	33	53

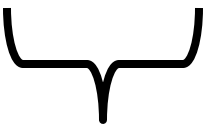

Target > key of midpoint? YES.

# Binary Search

Example: sorted array of integer keys. Target=7.

[ 0 ]	[ 1 ]	[ 2 ]	[ 3 ]	[ 4 ]	[ 5 ]	[ 6 ]
3	6	7	11	32	33	53

Search for the target in the area after midpoint.

# Binary Search

Example: sorted array of integer keys. Target=7.

[ 0 ]	[ 1 ]	[ 2 ]	[ 3 ]	[ 4 ]	[ 5 ]	[ 6 ]
3	6	7	11	32	33	53

Find approximate midpoint.  
Is target = midpoint key? YES.

- Average and worst case of serial search =  $O(n)$
- Average and worst case of binary search =  $O(\log_2 n)$

```
int binarySearch(T key)  
    return bsearch(0,  $n - 1$ , key)
```

```
int bsearch(int low, int high, T key)  
    if  $low > high$  then  
        throw KeyNotFoundException  
    else  
         $mid = \lfloor (low + high) / 2 \rfloor$   
        if ( $A[mid] > key$ ) then  
            return bsearch(low,  $mid - 1$ , key)  
        else if ( $A[mid] < key$ ) then  
            return bsearch( $mid + 1$ , high, key)  
        else  
            return mid  
        end if  
    end if
```

# Binary Search Pre-Condition 1

## Precondition 1:

- a)  $A$  is an array with length  $A.length = n \geq 1$  storing values of some *ordered* type  $T$
- b)  $A[i] < A[i + 1]$  for every integer  $i$  such that  $0 \leq i < n - 1$
- c)  $key$  is a value of type  $T$  that is stored in  $A$
- d)  $low$  and  $high$  are integers such that
  - $0 \leq low \leq n$
  - $-1 \leq high \leq n - 1$
  - $low \leq high + 1$
  - $A[h] < key$  for  $0 \leq h < low$
  - $A[h] > key$  for  $high < h \leq n - 1$

# Binary Search Pre-Condition 2

## Precondition 2:

- a)  $A$  is an array with length  $A.length = n \geq 1$  storing values of some *ordered* type  $T$
- b)  $A[i] < A[i + 1]$  for every integer  $i$  such that  $0 \leq i < n - 1$
- c)  $key$  is a value of type  $T$  that is *not* stored in  $A$
- d)  $low$  and  $high$  are integers such that
  - $0 \leq low \leq n$
  - $-1 \leq high \leq n - 1$
  - $low \leq high + 1$
  - $A[h] < key$  for  $0 \leq h < low$
  - $A[h] > key$  for  $high < h \leq n - 1$

- Confirm that the one of the preconditions for the subroutine is satisfied whenever the subroutine is called by the main algorithm (with  $low = 0$  and  $high = n-1$ ), if  $A$  is a sorted array with length  $n$ .

***int bsearch(int low, int high, int key)***

Confirm that the preconditions for the bsearch subroutine each imply that key is not an element of the array A if  $high = low - 1$ .

d) *low* and *high* are integers such that

- $0 \leq low \leq n$
- $-1 \leq high \leq n - 1$
- $low \leq high + 1$
- $A[h] < key$  for  $0 \leq h < low$
- $A[h] > key$  for  $high < h \leq n - 1$

- Confirm that preconditions for the bsearch subroutine each imply that key is not an element of the array A if  $\text{high} = \text{low} - 1$ .

- Confirm that each of the preconditions implies that if  $\text{low} = \text{high}$  then either  $A[\text{low}] = \text{key}$  or key is not an element of the array at all.

## In case $\text{Low} \geq \text{High}$

- We can argue that if `bsearch` is called with either of its **preconditions satisfied**, and with  **$\text{low} \geq \text{high}$** , then `bsearch` produces the output it should: The corresponding postcondition is satisfied on termination of the algorithm, because the **algorithm returns an index  $h$  such that  $A[h] = \text{key}$**  if `key` is an element of the array, and it throws a **`NotFoundException`** otherwise.

## In case $\text{low} < \text{high}$ :

- Argue that if either one of the subroutine's preconditions is satisfied when the algorithm is called, and the algorithm then calls itself recursively, then the same precondition is still satisfied — and the array  $A$  and value  $\text{key}$  have not been changed — at the beginning of the recursive call that is made.

- Suppose:

$$\text{high} - \text{low} + 1 = 2^h$$

```
int bsearch(int low, int high, T key)  
  if low > high then  
    throw KeyNotFoundException  
  else  
    mid =  $\lfloor (\text{low} + \text{high}) / 2 \rfloor$   
    if (A[mid] > key) then  
      return bsearch(low, mid - 1, key)  
    else if (A[mid] < key) then  
      return bsearch(mid + 1, high, key)  
    else  
      return mid  
    end if  
  end if
```

- Suppose:  
 $high = low + 2h$

Show that *if* `bsearch` calls itself recursively, *then* it does so to search a part of the array that has length at most  $h$  in this case, as well.

```
int bsearch(int low, int high, T key)  
  if low > high then  
    throw KeyNotFoundException  
  else  
    mid =  $\lfloor (low + high) / 2 \rfloor$   
    if (A[mid] > key) then  
      return bsearch(low, mid - 1, key)  
    else if (A[mid] < key) then  
      return bsearch(mid + 1, high, key)  
    else  
      return mid  
    end if  
  end if
```

# Analysis of running time

- Show that if the Binary Search is run on an array of length  $n$ , for  $n \geq 1$ , then the total number of calls made to `bsearch` is at most  $\log_2 n + 2$ .

# Time Complexity of binarySearch

- Call  $T(n)$  the time of binarySearch when the array size is  $n$ .
- $T(n) = T(n/2) + c$ , where  $c$  is some constant representing the time of the basis step and the if-statement
- Assume for simplicity that  $n = 2^k$ . (so  $k = \log_2 n$ )
- $T(2^k) = T(2^{k-1}) + c = T(2^{k-2}) + c + c = T(2^{k-3}) + c + c + c = \dots = T(2^0) + c + c + \dots + c = T(1) + kc = O(k) = O(\log n)$
- Therefore,  $T(n) = O(\log n)$ .
